2.1 Open set

A set $\mathcal{A}$ is said to be an open set if for every $\underline{x} \in \mathbb{R}^n$, we can find $\epsilon > 0$ such that,

$$B_\epsilon(\underline{x}) \subseteq \mathcal{A} \tag{2.1}$$

Where $B_\epsilon(\underline{x})$ is an n-dimensional ball with radius ϵ and center $\underline{x}$. No matter which point we are taking , it's always lie within the set. open sets are typically denoted as ().

2.2 Close set

A set is said to be close set if:

- If compliments of the set is an open set.
- Points lies outside the sets has a neighborhood disjoint point from the set.
- If every limits point of the set lies inside the set.
- It is denoted as [].

2.3 Convex set

$\mathcal{A}$ is said to be a convex set if, $\forall\ \underline{x} \in \mathcal{A}$ and $\forall\ 0 \leqslant \alpha \leqslant 1$

$$\alpha\underline{x} + (1-\alpha)\underline{y} \in \mathcal{A} \tag{2.2}$$

Geometrically, if we consider any two points inside the set, then every point that lies on the line that joins these two points must lie inside the set.

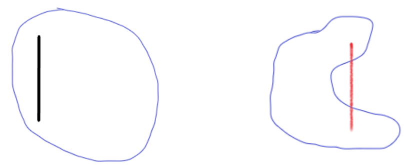

Figure 2.1: (a)Convex set (b) Not a convex set

Example : Achievable rate regions are convex: a time-sharing argument : Consider a multi-user system where we have some L-transmitter and L-receiver and they want to communicate through the channel described in figure [fig3]. We want to find the achievable rate over this channel.

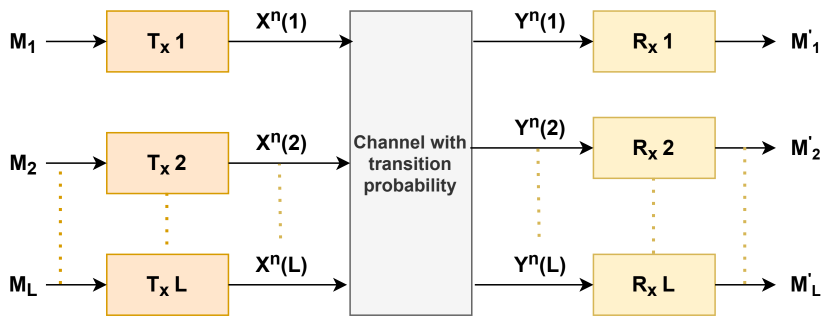

Figure 2.2: (a) Transceiver for L-transmitter and Receiver setting

A rate tuple $(R_1, R_2 \ldots R_L)$ is achievable if $\exists$ pair of encoder and decoder.
$(ENC_n(1), ENC_n(2), \ldots ENC_n(l), DEC_n(1), DEC_n(2) \ldots, DEC_n(l))$ pair can be define as :
$ENC_n(i) : \{0,1\}^{K_n(i)} \longrightarrow \mathcal{X}^n(l)$ and , $DEC_n(i) : \mathcal{Y}^n(l) \longrightarrow \{0,1\}^{K_n(l)}$ such that :

$$\limsup_{\text{n} \to \infty} \frac{K_n(i)}{n} = R_i \tag{2.3}$$

$$\limsup_{\text{n} \to \infty} Pr\left[M'_i \neq M_i\right] = 0 \tag{2.4}$$

And we want to find what kind of rate can be achievable. Consider the tuple (R_1, R_2) which is achievable. According to the Shannon coding theorem, any rate less than the capacity of the channel is achievable. So, rate region for the single $T_X - R_X$ is a close interval which is $[0, C]$.

For 2 user Case :
Theorm : Every rate region are convex. i.e if $(R_1, R_2)\,\&\,(R'_1, R'_2)$ are achievable and it lie in the convex set then $\forall\ 0 \leqslant \alpha \leqslant 1, \quad (\alpha R_1 + (1-\alpha)R'_1, \alpha R'_2 + (1-\alpha)R_2,)$ is achievable.
Proof : Consider a time sharing problem (R_1, R_2) and (R'_1, R'_2) for ENC and DEC pair such that :
$K_n(1) \geqslant n\,(R_1 - \epsilon)$ and $K_n(2) \geqslant n\,(R_2 - \epsilon)$ for (ENC, DEC). $K'_n(1) \geqslant n\,(R'_1 - \epsilon)$ and $K'_n(2) \geqslant n\,(R'_2 - \epsilon)$ for (ENC', DEC')
We have n-channel uses and consider αn times channel used by first $(ENC - DEC)$ pair and $(1-\alpha)\,n$ for $(ENC' - DEC')$ pair. Hence

$$\alpha K_n(1) \geqslant \alpha n\,(R_1 - \epsilon) \tag{2.5}$$

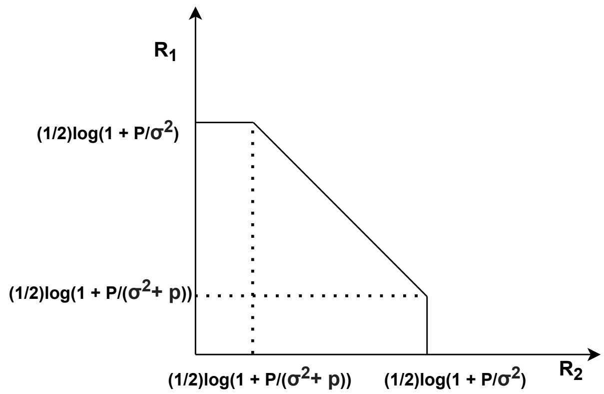

Figure 2.3: 2 user rate tuple case

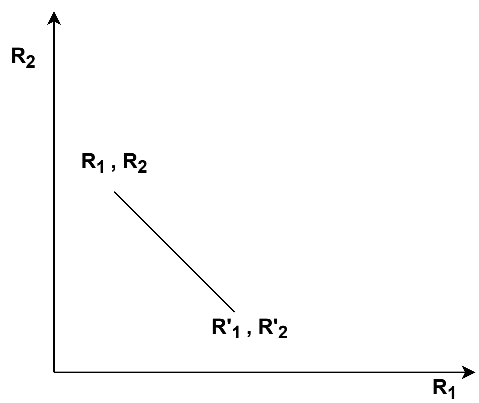

Figure 2.4: 2 user rate case

$$\alpha K_n(2) \geqslant \alpha n \left(R_2 - \epsilon\right) \tag{2.6}$$

and,

$$(1-\alpha)\, K'_n(1) \geqslant (1-\alpha)\, n \left(R'_1 - \epsilon\right) \tag{2.7}$$

$$(1-\alpha)\, K'_n(2) \geqslant (1-\alpha)\, n \left(R'_2 - \epsilon\right) \tag{2.8}$$

Combining [2.5], [2.7] and [2.6], [2.8], we have

$$\alpha K_n(1) + (1-\alpha)\, K'_n(1) \geqslant \alpha n \left(R_1 - \epsilon\right) + (1-\alpha)\, n \left(R'_1 - \epsilon\right) \tag{2.9}$$

$$\alpha K_n(2) + (1-\alpha)\, K'_n(2) \geqslant \alpha n \left(R_2 - \epsilon\right) + (1-\alpha)\, n \left(R'_2 - \epsilon\right) \tag{2.10}$$

And it holds $\forall\ \epsilon > 0$.
